

CLEAN VERSION OF AMENDMENTS

IN THE CLAIMS

Please amend claims 1, 6, and 8 to read as follows. All claims are reprinted below for the convenience of the Examiner.

1 (four times amended). A memory system, comprising:

a plurality of defect-adaptive memory devices, each of said plurality of defect-adaptive memory devices having a first region for sequentially storing parity information for data recovery and a second region for storing data;

a plurality of caches, each of said plurality of caches respectively coupled operatively to a corresponding unique one of said plurality of defect-adaptive memory devices, each of said plurality of caches adapted for storing parity information for data recovery for a corresponding unique one of said plurality of defect-adaptive memory devices; and

a controller operatively coupled to each defect-adaptive memory device of said plurality of defect-adaptive memory devices and to each corresponding cache of said plurality of caches, said controller comprising a first means for selectively controlling writing and reading of parity information needed for data recovery in said first region of each corresponding one of said plurality of defect-adaptive

15 memory devices, a second means for selectively obtaining parity information
16 needed for data recovery from said first region of each corresponding one of said
17 plurality of defect-adaptive memory devices, and a third means for selectively
18 storing parity information needed for data recovery obtained from said first region
19 of a corresponding one of said plurality of defect-adaptive memory devices in a
20 predetermined corresponding one of said plurality of caches.

2 (thrice previously amended, unchanged herein). The memory system of claim 1,
2 wherein said controller comprises a means for determining whether data recovery
3 information is stored in any cache of said plurality of caches.

1 Sub
G1 3 (thrice previously amended, unchanged herein). The memory system of claim 1,
2 wherein the parity information needed for data recovery is stored and is sequentially
3 arranged from the most outer cylinder on a recording medium in each corresponding one
4 of said plurality of defect-adaptive memory devices.

1 4 (thrice previously amended, unchanged herein). The memory system of claim 3,
2 wherein parity information for data recovery is modified to a value obtained through a
3 calculation of new data recovery information.

1 5 (thrice previously amended, unchanged herein). The memory system of claim 4,
2 wherein parity information for data recovery is obtained by performing an exclusive-OR
3 operation on previous data, parity information corresponding to the previous data, and
4 new data.

5 6 (four times amended). A redundant array of inexpensive disks (RAID) system,
6 comprising:

7 a plurality of disk drives, each of said plurality of disk drives including a first region
8 having a plurality of data blocks for storing data and a second region having a
9 predetermined number of parity blocks for storing parity information for data
10 recovery;

11 a plurality of caches, each of said plurality of caches respectively coupled operatively to a
12 corresponding unique one of said plurality of disk drives, each of said caches
13 adapted for storing parity information for data recovery; and

14 a controller operatively coupled to each disk drive of said plurality of disk drives and to
15 each corresponding cache of said plurality of caches, said controller adapted for
16 selectively controlling a write operation of data and parity information for a data
17 recovery in each corresponding disk drive of said plurality of disk drives, said

14 controller comprising:

15 a first means for selecting a single predetermined disk drive of said plurality
16 of disk drives upon receipt of a data writing instruction from a host
17 computer;

18 a second means for reading old data from the single predetermined disk
19 drive of said plurality of disk drives;

20 a third means for determining whether old parity information corresponding
21 to the old data corresponding to the single predetermined disk drive
22 of said plurality of disk drives is accessed in a corresponding single
23 cache of said plurality of caches;

24 a fourth means for reading the old parity information from the single
25 predetermined disk drive of said plurality of disk drives, upon the old
26 parity information corresponding to the single predetermined disk
27 drive of said plurality of disk drives not being accessed in the
28 corresponding single cache of said plurality of caches, and for then
29 loading the corresponding single cache of said plurality of caches
30 with the old parity information;

31 a fifth means for obtaining new parity information by performing an
32 exclusive OR operation on the old data, the old parity information

33 and new data;

34 a sixth means for loading the corresponding single cache of said plurality of
35 caches with the new parity information;

36 a seventh means for writing the new data in said region for storing data in
37 the single predetermined disk drive of said plurality of disk drives
38 and writing the new parity information in said another region for
39 storing parity information in the predetermined single disk drive of
40 said plurality of disk drives; and

41 an eighth means for reading old parity information from the single pre-
42 determined disk drive after the seventh means has written new data
43 in said region for storing data and has written the new parity infor-
44 mation in said another region for storing parity information, in the
45 event that no old parity information exists in a corresponding cache,
46 and for then moving said old parity information read from the single
47 predetermined disk drive to the corresponding cache to provide an
48 update of the parity information.

1 7. (unchanged). In a method of writing data to, and reading data from, a
2 redundant array of inexpensive disks (RAID) system, said method comprising steps for

3 sequentially storing information for data recovery in a first region of a disk, storing
4 information comprising data in a second region of the disk other than the first region,
5 controlling writing and reading of information by means of an electronic controller unit,
6 and caching information for data recovery, *the improvement comprising* a step for
7 reducing overhead during a read operation for data recovery and thereby improving data
8 input-output performance.

1
2 8 (amended). The method of claim 7, wherein said step for reducing overhead
3 during a read operation for data recovery and thereby improving data input-output
4 performance comprises steps for:

5 (a) coupling each one of a plurality of caches to each corresponding unique one of
6 a plurality of disks, whereby each disk is coupled to one unique cache;

7 (b) operatively coupling the caches to the controller;

8 (c) storing in each unique one of the plurality of caches information for data
9 recovery in the unique one disk corresponding to the unique one cache; and

10 (d) determining information for data recovery in a disk by using information for
data recovery stored in the unique one cache corresponding to the unique one disk.
